24 v.

25 GOOGLE INC.

26 Defendant.

Case No. CV 10-03561 WHA

**ORACLE'S MAY 10, 2012 BRIEF  
RESPONDING TO COURT'S  
QUESTIONS ON  
COPYRIGHTABILITY**

Dept.: Courtroom 8, 19th Floor  
Judge: Honorable William H. Alsup

1           **1. If the Copyright Act is meant to protect expression but not vocabulary,**  
2           **should the vocabulary and grammar of a computer language be copyrightable, as**  
3           **distinct from programs written in the language? In this regard, please comment on**  
4           **the May 2, 2012, decision of the High Court of the European Union.**

5           Protectability of a computer programming language is not the issue in this case. However,  
6           if sufficiently original and creative, the vocabulary and grammar of a computer language may be  
7           protected by copyright. In *Reiss v. National Quotation Bureau, Inc.*, Judge Learned Hand upheld  
8           copyright protection for a code book containing coined words that could be assigned an agreed  
9           meaning for use in cable correspondence. 276 F. 717, 718-19 (S.D.N.Y. 1921). Similarly, in  
10          *Hatfield v. Peterson*, the Second Circuit upheld copyright protection for a telegraphic code that  
11          was a compilation of non-original words and phrases, holding “the copyright is valid because of  
12          the originality of the combination.” 91 F.2d 998, 1000 (2d Cir. 1937). An individual word alone  
13          is not protectable, but if sufficiently original, the selection and combination of a collection of  
14          vocabulary words in a programming language should be protectable under these same principles.

15          Although the threshold of originality may be more difficult to meet, the same applies to  
16          the grammar evaluated in combination with that vocabulary. The grammar potentially adds to the  
17          originality of the combination and arrangement of the words and, if sufficiently creative, merits  
18          protection. *See Toro Co. v. R & R Prods*, 787 F.2d 1208, 1213 (8th Cir. 1986) (“A system that  
19          uses symbols in some sort of meaningful pattern, something by which one could distinguish effort  
20          or content, would be an original work.”). (*See also* ECF No. 900 at 1-5.)

21          The recent decision of the Court of Justice of the European Union (“CJEU”) states that  
22          programming languages might be protected as copyrighted works if they are their author’s own  
23          intellectual creation. Case C-406/10 *SAS Institute, Inc. v. World Programming Ltd.*, Judgment  
24          (May 2, 2012) ¶ 45. The *SAS* case was a reference, which asked for guidance from the CJEU on  
25          a series of questions. The first set of questions concerned copyright protection for programming  
26          languages, the functionality of a computer program and the format of data files. *SAS* ¶ 29.

27          In *SAS*, the CJEU addressed the potential copyrightability of these components under two  
28          EU “directives:” Directive 91/250 (the “Software Directive”) and Directive 2001/29 (the  
“Copyright Directive”). The Software Directive applies to computer programs (*see id.* ¶ 8(7),

1 9(2)); the Copyright Directive has more general application. *See id.* ¶ 15 (2). The court  
 2 concluded that a programming language is not protected under the Software Directive: “neither  
 3 the functionality of a computer program nor the programming language and the format of data  
 4 files used in a computer program to exploit certain of its functions constitute a form of expression  
 5 of that program for the purposes of Article 1(2) of Directive 91/250.” *Id.* ¶ 39.<sup>1</sup>

6 A programming language *could* be copyrightable under the Copyright Directive, however:

7 The Court also points out that the finding made in paragraph 39 of the present  
 8 judgment cannot affect the possibility that the SAS language and the format of  
 9 SAS Institute’s data files might be protected as works by copyright under  
 Directive 2001/29 if they are their author’s own intellectual creation.

10 *Id.* ¶ 45 (citation omitted). The CJEU decision thus concludes computer programming languages  
 11 may be copyrightable if they are sufficiently original. As the Court may recall, Advocate General  
 12 Bot had recommended, in a non-binding opinion, that the CJEU find that programming languages  
 13 were not copyrightable. *SAS Institute, Inc. v. World Programming Ltd.*, Case C-406/10 (Nov. 29,  
 14 2011) ¶ 75. (*See* ECF Nos 852, 859). The CJEU declined to adopt that part of his opinion.

15 The portion of the SAS case that is more analogous to the present circumstances, however,  
 16 concerns the set of questions relating to the defendant’s copying of the SAS user manual. The  
 17 CJEU held that copying from the SAS user manual into defendant’s own user manual and  
 18 computer program could also constitute infringement under the Copyright Directive:

19 Consequently, in the light of the foregoing considerations, the answer to Questions  
 20 8 and 9 is that Article 2(a) of Directive 2001/29 must be interpreted as meaning  
 21 that the reproduction, in a computer program or a user manual for that program, of  
 22 certain elements described in the user manual for another computer program  
 protected by copyright is capable of constituting an infringement of the copyright  
 in the latter manual if—this being a matter for the national court to ascertain—that  
 reproduction constitutes the expression of the intellectual creation of the author of  
 the user manual for the computer program protected by copyright.

23 *Id.* ¶ 70.

24 Notably, the court found that, while elements described in the SAS manual—including

25 <sup>1</sup> SAS was only released recently and commentators are still analyzing it. It is unclear  
 26 whether the court found programming languages are not covered by the Software Directive  
 27 because they are not “computer programs” as the Directive requires (*see id.* ¶¶ 8(7), 9(2)) or  
 28 because, while they are computer programs, they lack sufficient “expression” within the meaning  
 of that Directive. The decision does state that the code relating to the programming language  
 would be protectable under the Software Directive as a computer program. *See id.* ¶ 43.

1 keywords, syntax and commands—could not be copyrighted individually, their “choice, sequence  
2 and combination” may warrant copyright protection as an intellectual creation of the author:

3 It is only through the choice, sequence and combination of those words, figures or  
4 mathematical concepts that the author may express his creativity in an original  
5 manner and achieve a result, namely the user manual for the computer program,  
6 which is an intellectual creation (see, to that effect, *Infopaq International*,  
7 paragraph 45.)

8 *Id.* ¶¶ 66-67.<sup>2</sup> Although *SAS* was decided under different law and involved very different facts  
9 (including no finding that the defendant had copied the structural design of the code (*id.* ¶ 25) and  
10 no issue about APIs), the CJEU decision supports a finding that Google’s copying of the SSO set  
11 forth in Oracle’s API documentation constitutes infringement.

12 **2. If each API method is a program — pre-packaged but nonetheless a  
13 program — did Google copy anything more than the name and the declaration  
14 (substituting its own implementation)?**

15 Yes. Google did not just copy the name and the declaration for each method. Google also  
16 copied the SSO of the 37 API packages. The method names and declaration it copied are an  
17 essential part of that SSO. (In this trial the term “method declaration” has often been used when  
18 “method header” is technically correct. Oracle will continue to use “declaration” in this brief.)

19 The method declarations Google copied include considerable original expression. The  
20 elements it copied include the mode (e.g. public or protected), the name, the parameter list, and  
21 the throws clause (exception list) of thousands of methods. (*See Java Language Specification 3d*  
22 Ed. (“JLS”) § 8.4, TX 984 at 209-237 (describing components of method header. *See also* RT  
23 1238:13-1239:12 (describing creativity in method declarations), 1249:2-12 (Mitchell).) Google  
24 copied all this into Android, including elements not required for “compatibility:”

25 Q. And roughly, what percentage of copying did you observe in your work?

26 \_\_\_\_\_  
27 <sup>2</sup> In the *Infopaq* case, the CJEU held the reproduction of extracts consisting of *eleven*  
28 *words of text* by a news summary service (5 words on either side of a key search word) fell within  
the scope of protection of the Copyright Directive. *Case C-5/08 Infopaq International A/S v.*  
*Danske Dagblades Forening*, [2009] ECR I-6569 (Attachment A). “[T]he possibility may not be  
ruled out that certain isolated sentences, or even certain parts of sentences in the text in question,  
may be suitable for conveying to the reader an element which is, in itself, the expression of the  
intellectual creation of the author of that article.” *Id.* ¶ 47. That was particularly true since the  
defendant’s data capture process “reproduces an extract of 11 words each time a search word  
appears in the relevant work” and allows clients to request more than one search word. *Id.* ¶ 49.

1 A. Quantitatively, approximately 90 percent. There's – occasionally there's  
2 something that's not copied, and occasionally there may be some small differences  
in the way things are named.

3 For example, the methods have parameters. Sometimes the parameter names are  
4 different. *Surprisingly, they're the same in probably two-thirds of the cases, even  
though that's not necessary for the library to be used in the same way by  
5 programmers.*

6 (RT 1248:11-1249:12 (Mitchell).) Google did not rebut this evidence at trial.

7 But this case is not based on the copying of individual methods. It is undisputed Google  
8 copied thousands of methods and other API elements and all of the relationships among them,  
9 replicating the structure, sequence and organization of Oracle's documentation and source code in  
10 the 37 packages. Google's expert concedes that this is the case. (RT at 2214:6-9 (Astrachan).)

11 The methods are a key part of that structure. Google chose to repeatedly emphasize a  
12 trivial example at trial, `java.lang.Math.max`. This method is unusually simple because (1) like  
13 other basic mathematical functions in the `java.lang.Math` class, it seems obvious to include it;  
14 (2) it does not depend at all upon any other methods but rather stands alone; and (3) it does not  
15 access data stored in the fields of any member of any class. It creates the misleading impression  
16 that the only creativity in method design is selecting the class and package in which to put it in.

17 In the more typical example, however, the methods are very much the product of creative  
18 design choices themselves. When an API designer sets out to design a new package, he or she  
19 faces many different possibilities for addressing the particular technical challenges involved. (*See*  
20 RT at 621:7-623:21 (Reinhold) (describing design process); 627:21-629:6 (discussing design  
21 choices).) There is no simple list of standalone functions like `java.lang.Math.max` to plug in. As  
22 Dr. Reinhold testified `java.lang.Math.max` does not accurately depict the work that goes into  
23 designing APIs. (*See* RT at 2228:2-16 (“max is a pretty trivial problem. In nio we had to solve a  
24 very hard problem, a portable high-performance IO API. And to do that we needed to design  
25 hundreds of methods, most of them much more complicated than max, organized into doesn't of  
26 Classes across a handful of different Packages.”).)

1           Methods are designed to work with other methods and classes in a way that is intuitive,  
2 effective, and best suits the goal of the API design. The design solution determines the methods  
3 and the methods reflect the structure of the design.

4           To give a very simple example, suppose you have a Screen class such that a member (or  
5 “instance”) of the class represents the display screen. If you want to be able to draw a rectangle,  
6 one possibility would be to create a method called “drawRect that takes an x, y coordinate, a  
7 height and width and draws the rectangle. The API might look like this:

```
8           public class Screen {
9                 public void drawRect(in x, int y, int width, int, height) { ... }
10           }
```

11           To draw a rectangle with this API you would first create an instance of the class, using the  
12 “new” keyword and then invoke the drawRect method, like so:

```
12           Screen s = new Screen();     /* Get a Screen object */
13           s.drawRect(10, 10, 10, 10);   /* Draw a 10x10 rectangle */
```

14           This code would produce a rectangle that is 10x10 pixels starting at the point 10 pixels  
15 down and 10 in from the top left of your screen.

16           A fundamentally different choice would be to create an API that allows the user to “draw”  
17 the rectangle using a “pen.” This design would include a different set of methods associated with  
18 it. The API could look like this:

```
19           public class Screen{
20                 public void dropPen(int x, int y) { ... }
21                 public void raisePen() {... }
22                 public void turn (int degrees) {... }
23                 public void draw(int length) { ... }
24           }
```

25           One way to draw the same rectangle, would be to do the following:

```
26           Screen s = new Screen();
27           s.dropPen(10, 10);
28           s.turn(90); s.draw(10);
29           s.turn(90); s.draw(10);
30           s.turn(90); s.draw(10);
31           s.turn(90); s.draw(10);
32           s.raisePen();
```

33           In this highly simplified example, neither API is inherently better than the other. The first  
34 is simpler, the second allows drawing other types of shapes. The methods used reflect the design

1 choice that was made. They do not arise inevitably from the decision to include a method for  
2 drawing a rectangle in the API.

3 The Court can view an actual example from Java in the method detail in TX 610.2 for  
4 `java.util.regex.Matcher.appendReplacement`. (TX 610.2 at `/docs/api/java/util/regex/`  
5 `Matcher.html`.) This method "[i]mplements a non-terminal append-and-replace step" within a  
6 class for matching patterns of text. Examining the code alone, the method header seems  
7 straightforward enough, taking two parameters and returning a value:

8 

```
public Matcher appendReplacement(StringBuffer sb, String replacement)
```

9 *Id.* But this seemingly simple header is followed by several paragraphs of specification text to  
10 explain how to use it and how it works with other methods in the `Matcher` class, with the `Pattern`  
11 class elsewhere in the `java.util.regex` package, and with the `StringBuffer` class in the `java.lang`  
12 package. The specification of the method includes 8 lines of example code to tell developers how  
13 to use the method. The simplicity of this method's design was hardly preordained—it was the  
14 result of concerted, creative effort.

15 Another useful example is to consider the different approach that Oracle and Google took  
16 in designing APIs for graphical user interfaces. If a Java developer wanted to create a dialog box  
17 with a simple message and a button marked "OK," she might use the method

18 

```
javax.swing.JOptionPane.showMessageDialog:  
JOptionPane.showMessageDialog(frame, "This text will be displayed", "Message");
```

19 See TX 610.2 at `/docs/api/javax/swing/JOptionPane.html`. Displaying a similar dialog box in  
20 Android would require the use of the `android.app.AlertDialog.Builder` API, which requires,  
21 among other things, separate steps for creating the dialog box, setting the message to be displayed  
22 (`AlertDialog.Builder.setMessage()`), setting the text to display on the button  
23 (`AlertDialog.Builder.setNegativeButton()`), and showing the dialog (`AlertDialog.create()`). See  
24 TX 767 at `/android/app/AlertDialog.Builder.html`.

25 As these examples show, method names, headers, and declarations are an integral part of  
26 the structure and themselves reflect API developer's design choices. Their selection, structure,  
27 sequence and organization is original and is protectable by copyright.  
28

1                   **3. If the format of the name is dictated by the Java programming rules, then is the form of “java.package.class.method” required by the syntax of the language itself?**

2  
3                   Yes, although the format of the names does not dictate an API designer’s choice of any  
4 particular structure, the format of fully-qualified method names must conform with the syntax of  
5 the language. But the fully qualified name can be richer than the example given in the question.  
6 A package name may contain an arbitrary number of elements, separated by periods. For  
7 example “java.lang” is a package name, and so is “java.util.concurrent.locks”. (See TX 610.2 at  
8 /jdk-1\_5\_0-doc/docs/api/overview-summary.html (list of packages).) Package names need not  
9 start with “java,” so “org.w3c.dom” is a package name as well. *Id.* Some of the packages that  
10 Android did not copy from Java begin with “android” instead of “java.” (See TX 767 at  
11 packages.html.; TX 984 at 154).

12                   There are also different structural possibilities permitted within the syntax. For example,  
13 Java allows nested “Member” classes, such as “java.nio.channels.Pipe.SinkChannel,” in which  
14 one class, SinkChannel, is enclosed within another class, Pipe. (See TX 984 at 210; TX 610.2 at  
15 /docs/api/java/nio/channels/Pipe.SinkChannel.html; TX 623 at \licensebundles\source-  
16 bundles\jdk-1\_5\_0-fcs-src-b64-windows-  
17 15\_sep\_2004.zip.zip\j2se\src\share\classes\java\nio\channels\Pipe.java, lines 69-98.) In the  
18 example above, the platform designers chose to declare the SinkChannel class within the source  
19 code file for the Pipe class, and that design choice is reflected in the fully qualified name.

20                   Java allows Member interfaces, where an interface is defined within another class or  
21 interface. This is also reflected in the fully-qualified name. (See, e.g., TX 984 at 237; TX 610.2  
22 at /jdk-1\_5\_0-doc/docs/api/java/lang/Thread.UncaughtExceptionHandler.html (documentation for  
23 interface java.lang.Thread.UncaughtExceptionHandler, which is enclosed in the file Thread).)

24                   **4. Could Google have come up with different names and SSO yet still have provided the same functionality as in Android? Android users would have had to learn a new vocabulary and a new outline but the methods would all still have been resident in such a modified Android. True? Is this what the UK company Spring did?**

25  
26  
27                   Yes, but with the caveat that if Google had done this one would not expect that “the  
28 methods would all still have been resident in such a modified Android.” That may be true for

1 very simple methods (e.g., Math.max), but more sophisticated methods would be designed for a  
2 completely different set of classes, interfaces, and packages. The high-level functionality could  
3 be the same as the copied Java APIs, but the actual set of methods would be quite different.

4 Both parties' experts testified that Google could have and did come up with its own APIs  
5 for Android with different names and SSO but with similar functionality to the Java APIs. (*See*  
6 RT 2288:6-12 (Mitchell); RT 2212:25-2213:19, 2220:1-7 (Astrachan).) *See also* TX 767 at  
7 packages.html (listing package names beginning with "android" compared to those beginning  
8 with "java" and "javax".)

9 In addition, Dr. Reinhold described an open source API and class library for much the  
10 same functionality as one of the Java API packages at issue, java.util.logging, but with a very  
11 different SSO. (RT at 630:11-631:18(Reinhold).) Mr. Screven testified there are also alternate  
12 Java APIs for mathematics and encryption. (RT at 518:4-519:15 (Screven).) Both of these  
13 programming areas are covered by the Java API packages at issue here. (*See* TX 1072 (listing  
14 logging, encryption and math packages among 37 accused packages).

15 The Court is correct that this is what SpringSource did:

16 There's a company in the UK that built its own Java environment. And they used  
17 the Java programming language, but they created their own set of APIs, prewritten  
18 programs. And that other environment is called Spring.

19 So Spring uses the Java programming language, but it doesn't use the Sun-created  
20 APIs. They have their own set of APIs and their own set of prewritten programs.

21 (RT 290:25-291:6 (Ellison).) Of course, creating new APIs was much more time consuming and  
22 expensive than what Google did here in its rush to bring Android to market:

23 Q. Does it take a period of time and expense and resources if you're going to go  
24 that route?

25 A. Yeah. Spring had to design their own APIs, and then they had to teach the  
26 developer community about these new APIs. And they had to persuade them that  
27 their collection of APIs, their library of programs, was in some ways better than  
28 the library of programs that Oracle and Sun had produced.

(*Id.* at 304:16-22.)

**5. Is the input-output (*i.e.*, argument and return) scheme of a method copyrightable? For example, can someone copyright the function of inputting an angle and outputting the cosine of that angle? If someone has a copyright on a**

1 **particular program to find cosines, does that copyright cover all other**  
 2 **implementations that perform the identical function (input = angle, output = cosine)?**

3 No, the input-output scheme for an individual method is not copyrightable. The SSO of  
 4 the API packages, which includes thousands of these individual methods, is expressive and  
 5 protectable in its own right. Courts have also held that a “a combination of unprotectable  
 6 elements is eligible for copyright protection only if those elements are numerous enough and their  
 7 selection and arrangement original enough that their combination constitutes an original work of  
 8 authorship.” *Satava v. Lowry*, 323 F.3d 805, 811 (9th Cir. 2003). Specifically, courts have held  
 9 that combinations of original data elements in software may be copyrightable. *See Merch.*  
 10 *Transaction Sys. v. Nelcela, Inc.*, 2009 U.S. Dist. LEXIS 25663, at \*58 (D. Ariz. Mar. 17, 2009)  
 11 (finding the “selection, coordination, and arrangement of the information contained in the Lexcel  
 12 software's database schema (non-literal elements) and source code (those involving copying of  
 13 table and column names)” constituted copyrightable subject matter.)

14 Oracle selected thousands of methods and gave them a complex, highly original SSO by  
 15 placing them in hundreds of classes within dozens of packages. (*See* RT 602:4-603:6, 628:22-  
 16 629:6 (Reinhold); RT 1248:11-1249-1 (Mitchell).) Google copied the SSO in virtually identical  
 17 fashion, even where Oracle provided different variants for the method. The class  
 18 `java.nio.IntBuffer`, for instance, has 4 different variants of the “get” method:

```
19     public abstract int get ()
20     public abstract int get (int index)
21     public IntBuffer get (int[] dst)
22     public IntBuffer get (int[] dst, int dstOffset, int intCount)3
```

23 Google copied each of these different versions of the methods as well. (Compare TX 610.2 at  
 24 `/jdk-1_5_0-doc/docs/api/java/nio/IntBuffer.html` with TX 767 at `java/nio/IntBuffer.html`).

---

25  
 26  
 27 <sup>3</sup> The parameter names in Java for this version of the “get” method are (int[] dst, int offset,  
 28 int length). As noted above, Google chose to copy Oracle’s parameter names about two-thirds of  
 the time. (RT 1248:11-1249:12 (Mitchell).)

1                   **6. Is it agreed that the following is true, at least as of 1996?**

2                   **The following were the core Java Application Programming**  
3                   **Interface: java.lang, java.util and java.io.**

4                   The record does not reflect a precise definition of the term “core.” If “core” means  
5                   “containing some classes mentioned in the initial version of the *Java Language Specification*,”  
6                   the answer is yes. But “core” should not be interpreted to mean that all of the contents of these  
7                   packages are necessary to the programming language. That is not the case. According to Dr.  
8                   Reinhold’s analysis, only 61 classes are mentioned in the normative text of the *Java Language*  
9                   *Specification* and, except for java.lang.Object, which is only partially specified, none is specified  
10                  in detail in the Language Specification. (TX 1062; RT 676:14-678:13, 684:16-685:2 (Reinhold);  
11                  RT 2196:1-4 (Astrachan), TX 984 at 6.) Dr. Bloch agreed only 60 classes are mentioned in the  
12                  *Java Language Specification*, but never stated what they were. (RT at 777:21-24 (Bloch). Of the  
13                  classes mentioned, almost all are in java.lang. TX 1062 (listing 55 classes from java.lang, 4  
14                  annotations from java.lang.annotation, 1 interface from java.io, and 1 interface from java.util).

15                  These packages have all greatly expanded since they were first released in 1996. Dr.  
16                  Mitchell testified at trial as to how the structure of java.util has changed over time as that package  
17                  has grown dramatically in size. (RT at 1243:13-1244:16 (“It was just a smaller library and there  
18                  were fewer concepts in it.”).) A comparison of TX 2564 and TX 610.2 shows that java.util had  
19                  only 14 classes, and 142 methods in 1996 compared to 86 classes and 1059 methods in version  
20                  5.0. Similarly, java.io grew from only 31 classes and 304 methods in 1996 to 78 classes and 753  
21                  interfaces in version 5.0. And java.lang grew from 64 classes and 462 methods in 1996 to 95  
22                  classes and 1089 methods today.

23                  The java.util package includes classes and interfaces for events, properties, and collections  
24                  (i.e., data structures such as lists, sets, and maps). java.lang includes classes for spawning and  
25                  managing programs running in other operating-system processes. The java.io package includes  
26                  not just basic input/output facilities but also classes for converting arbitrary Java data objects to  
27                  and from streams of bytes which can be stored in a file or transmitted over a network. No  
28                  experienced developer would expect such facilities to be part of a programming language *per se*.

1 At the hearing on May 9, the Court suggested the Java programming language may not  
2 include concepts that are more commonly found in other languages. Nothing in the record  
3 supports this. The only evidence at trial comparing the contents of the Java language to the  
4 contents of other programming languages was the testimony of Dr. Reinhold who, at the Court's  
5 request, compared the enormously popular C programming language "to the Java programming  
6 language, ignoring all of the APIs." (RT at 640:5-24.) Dr. Reinhold stated that the Java  
7 programming language is much richer, like comparing a rocket to "a DC-3." (RT at 640:18-24.)

8 **7. Does the Java programming language refer to or require any method,  
9 class or package outside the above three?**

10 The package `java.lang.annotation` was added to the platform in J2SE 5.0. There are four  
11 annotations from `java.lang.annotation` that are referenced in the third edition of the *Java*  
12 *Language Specification*, TX 984, the edition of the JLS which corresponds to Version 5. There is  
13 only one interface from `java.io` and one class from `java.util` that are referenced in TX 984. All of  
14 the remaining classes come from the `java.lang` package. (See TX 1062.)

15 **8. To what extent do subparts of the above three Java packages refer to  
16 any other Java packages or subpart of other packages (meaning outside the three)?  
17 To the extent this occurs, should those outside subparts be deemed to be "core" to  
18 the programming language?**

19 The classes in the above three Java packages in J2SE 5.0 contain 85 direct references to  
20 classes, methods, or fields in 9 other packages. Those 9 packages are: `java.lang.annotation`,  
21 `java.lang.reflect`, `java.math`, `java.net`, `java.nio`, `java.nio.channels`, `java.nio.charset`, `java.security`  
22 and `java.util.regex`. If the search is limited to start with the 61 classes in these three Java  
23 packages that are actually mentioned in the JLS, including the 4 mentioned in  
24 `java.lang.annotation`, then there are just 30 direct references to elements in 5 other packages.  
25 Those packages are: `java.lang.reflect`, `java.net`, `java.nio`, `java.nio.channels`, and `java.security`.

26 The additional elements that are referenced are not "core" to the programming language.  
27 These references are in no way required by the JLS. They are, rather, due to the unconstrained  
28 choices made by the authors of the API specifications. As noted above the JLS mentions just 61  
classes by name, but in most cases does not require them to have any particular methods or fields.  
The JLS does specify some methods, constructors, and fields for about 20 different classes, but

1 none of these specified elements references any element located outside of java.lang, java.io, or  
2 java.util. It would be wrong to say that a class or method is somehow “core” to the language  
3 simply because another class refers to it.

4 **9. What cross-method, cross-class interdependencies exist at the**  
5 **implementation level in Java? Were any of these duplicated in the Android**  
6 **implementations? (The judge remembers no evidence on this point.)**

7 All of the cross-method, cross-class interdependencies that are present in the APIs exist at  
8 the implementation level in Java and in Android for the 37 API packages that Google copied.  
9 Both parties agree the documentation and the implementation are drawn from the source code.  
10 The experts agree the SSO is the same. (*See* RT 1248:11-1249:25 (Mitchell) RT 2214:6-9  
(Astrachan).)

11 In addition, many of the same cross-class relationships that exist at the declaration or  
12 method header level also exist at the implementation level. For example, a method might have a  
13 parameter list that includes a type defined in a different class. (*See* RT 602:18-603:4 (Reinhold)  
14 (discussing demonstrative method with class Color as a parameter).) It would make little sense  
15 for a method to take parameters as input—whether defined in the same class or another class—  
16 and then not use the parameters in the implementation.

17 With respect to implementation details that are unrelated to declarations and method  
18 headers, there are many cross-method, cross-class interdependencies between classes and  
19 packages in the Java implementation. Oracle did not submit any evidence at trial about the extent  
20 to which any of those additional interdependencies were copied by Android.

21 **10. In Java, what interdependencies exist at the name/declaration level**  
22 **other than the inherited characteristics from the super class, interfaces, same class,**  
23 **etc.? Please explain.**

24 At the level of method headers, dependencies upon other classes can occur in return and  
25 parameter types and in exception lists (“throws” clauses) (JLS 8.4, p. 210). A field declaration  
26 can refer to a class as the type of the field's values (JLS 8.3, p. 196). A class declaration places a  
27 class within a specific package and it can refer to a superclass and also to some implemented  
28 interfaces (JLS 8.1, p. 175), and similarly for interface declarations (JLS 9.1, p. 260). One can  
find a number of interdependencies reflecting original design choices in the declarations within

1 the Java platform. The choices of which parameters to include and the order in which to include  
 2 them illustrate such interdependencies, because parameter types can come from other classes and  
 3 packages. (See RT 602:18-603:4 (Reinhold).) The class `java.net.Authenticator`, for instance, has  
 4 three different versions of a method called “`requestPasswordAuthentication`.” (TX 610.2 at jdk-  
 5 1\_5\_0-doc/docs/api/java/net/Authenticator.html.) The parameter list for the most detailed of  
 6 these contains eight different parameters:

```
7      public static PasswordAuthentication requestPasswordAuthentication(String host,
8                               InetAddress addr,
9                               int port,
10                              String protocol,
11                              String prompt,
12                              String scheme,
13                              URL url,
14                              Authenticator.RequestorType reqType) {
```

11 *Id.* With the exception of “`int`,” which is a primitive type, each of the other parameters in this list  
 12 is a type of class. `InetAddress`, `URL`, and `Authenticator.RequestorType` are classes within `java.net`,  
 13 and `String` is specified in `java.lang`. Regardless of where in the specifications each parameter type  
 14 is defined, however, requiring eight different input values in the order the developers chose to  
 15 generate “[t]he username/password, or null if one can't be gotten,” *id.*, was a creative, nontrivial  
 16 choice that could have been structured differently, for example by putting these parameters in a  
 17 different method or class.

18 The list of exceptions a method throws also represents the expression of a structural  
 19 choice. The API designer must choose which exceptions to handle within a given method and  
 20 which code that calls the method will have to handle, or “catch” See TX 984 at 325-26. For  
 21 example, the class `java.security.cert.Certificate` contains a method identified with the header:

```
22      public abstract void verify(PublicKey key, String sigProvider) throws
23      CertificateException, NoSuchAlgorithmException, InvalidKeyException,
24      NoSuchProviderException, SignatureException
```

25 TX 610.2 at /docs/api/java/security/cert/Certificate.html. This method throws five different types  
 26 of exceptions. The designers could have chosen to have the method throw a single type of  
 27 exception or none.

28 **11. With respect to the Seventh Circuit decision in *American Dental Association*:**

1 (A) To what extent has it been adopted in the Ninth Circuit?

2 *American Dental Association v. Delta Dental Plans Association* (“ADA”), 126 F.3d 977  
3 (7<sup>th</sup> Cir. 1997) has not been cited in a published opinion within the Ninth Circuit. In reaching its  
4 conclusion that the dental procedure taxonomy was protectable, however, the ADA court  
5 expressly relied on two Ninth Circuit decisions: *Practice Management Information Corp. v.*  
6 *American Medical Association*, 121 F.3d 516 (9th Cir. 1997) (see ADA at 978), and *Edwin K.*  
7 *Williams & Co. v. Edwin K. Williams & Co. East*, 542 F.2d 1053 (9th Cir. 1976) (see ADA at  
8 981). In *Management Info.*, the Ninth Circuit affirmed the validity of the AMA’s copyright in its  
9 catalog of medical procedure codes and descriptions (“Current Procedural Terminology” or  
10 “CPT”). 121 F.3d at 520. The CPT “identifies more than six thousand medical procedures and  
11 provides a five-digit code and brief description for each.” *Id.* at 517. The court rejected  
12 plaintiff’s argument that the CPT had entered the public domain when a federal health care  
13 agency adopted the CPT codes for administering its programs. *Id.* at 517-518. The court  
14 observed that “copyrightability of the CPT provides the economic incentive for the AMA to  
15 produce and maintain the CPT” and “invalidating its copyright on the ground that the CPT  
16 entered the public domain when [agency] required its use would expose copyrights on a wide  
17 range of privately authored model codes, standards, and reference works to invalidation.” *Id.* at  
18 518-19.

19 In the second case, *Edwin K. Williams*, the Ninth Circuit upheld the validity of copyrights  
20 on plaintiff’s account books. 542 F.2d at 1060-61. The account books contained blank forms and  
21 instructions for the forms. *Id.* at 1060. One form, for example, was entitled “Stamp Control  
22 Promotion” and had a description that began “This section offers an easy method of accounting  
23 for Stamps or Promotion Items.” *Id.* The court held that “the instructions and the blank forms  
24 constituted an integrated work entitled to copyright protection.” *Id.* at 1061.

25 Similarly, in *Educational Testing Serv. v. Simon*, the court found that plaintiff’s  
26 copyrights in standardized test questions and forms were infringed, noting that the “headings and  
27 layout of defendants’ materials further make clear that their ‘sample’ questions were created  
28 through access to ETS’s copyrighted questions provided orally through students who previously

1 took the test.” 95 F. Supp. 2d 1081, 1088 (C.D. Cal. 1999). The court held that “ETS’ selection  
2 of topics for a particular test form is an exercise requiring judgment and creativity, and is  
3 therefore copyrightable.” *Id.* at 1089.

4 **(B) If the taxonomy in that decision was protectable, why  
5 shouldn’t Sun’s hierarchical outline of packages, classes,  
6 methods for the 37 API packages be protectable (other than  
perhaps the three core packages?)**

7 The SSO for the 37 Java API packages is protectable. It is far more intricate and creative  
8 than the dental code taxonomy at issue in the *ADA* case. The fact and expert witnesses from both  
9 sides testified that API design is highly creative and challenging. (RT 513:14-18 (Screven);  
10 627:21-628:1 (Reinhold); 751:5-752:14 (Bloch); 2209:7-8 (Astrachan); TX 624 at 47 (Bloch  
11 presentation).) It took Dr. Reinhold and a team of engineers almost two years to develop java.nio  
12 and its related sub-packages. (RT 623:17-624:1.)

13 *ADA* recognized that taxonomies are creative works entitled to copyright protection.  
14 *ADA*, 126 F.3d at 979 (Facts do not supply their own principles of organization. Classification is  
15 a creative endeavor.) But unlike a taxonomy, the 37 API packages do not simply classify existing  
16 data. They result from the many creative design choices made by Sun’s engineers from among  
17 numerous possibilities for addressing technical challenges. (RT 627:21-628:23 (Reinhold).) The  
18 SSO warrants protection under the principles expressed in the *ADA* decision. The java.lang,  
19 java.io, java.util packages packages are protectable as well, for the reasons discussed in section 6.

20 **(C) Did *ADA* hold that the numbering system alone (apart  
21 from the description) was copyrightable?**

22 Yes. *See ADA*, 126 F.3d at 979 (“The number assigned to any one of the three  
23 descriptions could have had four or six digits rather than five; guided tissue regeneration could  
24 have been placed in the 2500 series rather than the 4200 series; again any of these choices is  
25 original to the author of a taxonomy, and another author could do things differently.”). The court  
26 recognized that “all three elements of the Code—numbers, short descriptions, and long  
descriptions, are copyrightable subject matter.” *Id.*

27 **12. With respect to the Ninth Circuit’s decision in *Kapes*:**

1                   **(A) *Kapes* stated “Whether CDN’s selection and**  
2                   **arrangement of the price lists is sufficiently original to merit**  
3                   **protection is not at issue.” 197 F.3d at 1256. If that was not**  
4                   **issue, what, if anything, did *Kapes* expressly say about SSO?**

5                   The Ninth Circuit did not rule on the selection and arrangement of the price lists in  
6                   *CDN v. Kapes*, 197 F.3d 1256, 1259 (9th Cir. 1999). But it did rely upon *Urantia Foundation v.*  
7                   *Maaherra*, 114 F.3d 955, 959 (9th Cir. 1997) summarizing its holding as “the arrangement of  
8                   divine revelations met the level of creativity required for copyright.” In that case, the Ninth  
9                   Circuit addressed the selection, arrangement and structure of papers purportedly containing the  
10                  answers of divine beings to questions, which it treated as a protectable compilation:

11                  In this case, the Contact Commission may have received some guidance from  
12                  celestial beings when the Commission posed the questions, but the members of the  
13                  Contact Commission chose and formulated the specific questions asked. These  
14                  questions materially contributed to the structure of the Papers, to the arrangement  
15                  of the revelations in each Paper, and to the organization and order in which the  
16                  Papers followed one another. We hold that the human selection and arrangement  
17                  of the revelations in this case could not have been so “mechanical or routine as to  
18                  require no creativity whatsoever.” *Feist*, 499 at 362.

19                  The *Urantia* case confirms that the Ninth Circuit will uphold selection, arrangement and structure  
20                  in a written document, and that the standard for creativity it applies is a low one.

21                   **(B) In what sense were the “prices CDN creates” in *Kapes* a**  
22                   **“compilation” within the meaning of the Copyright Act (see**  
23                   **197 F.3d at 1260, second col.).**

24                  Under 17 U.S.C. § 101, “A ‘compilation’ is a work formed by the collection and  
25                  assembling of preexisting materials or of data that are selected, coordinated, or arranged in such a  
26                  way that the resulting work as a whole constitutes an original work of authorship.” The court  
27                  agreed with the district court’s finding that “the prices in CDN’s guides are not facts, they are  
28                  ‘wholly the product of [CDN’s] creativity.’” *Id.* (substitution in original). But at the same time,  
29                  CDN derived its price estimates by looking at wholesale prices, dealer online networks, public  
30                  auctions, private sales and other things, and exercising its own judgment in determining whether,  
31                  and to what extent, to rely on each. *Id.* It appears the court concluded that, because the prices  
32                  were based on data gathered from various sources, guides constituted a compilation of that data,  
33                  even if infused with creativity. It referred to them as “compilations of data chosen and weighed  
34                  with creativity.” *Id.* at 1261.

1                                   **(C) Didn't *Kapes* treat the coin prices as "compilations"?**  
2                                   **Please explain how this was done. Has Oracle abandoned the**  
3                                   **compilation argument herein?**

4           Yes. The case refers to the coin prices as "compilations" multiple times. It analyzed the  
5           copyrightability of the prices as though they were compilations, citing the *Urantia* case and  
6           concluding that the process for arriving at the prices was sufficiently original to be copyrightable,  
7           even if the underlying factual data was not. *Id.* at 1260.

8           The evidence here does not support that the API packages were "formed by the collection  
9           of preexisting materials or of data[.]" 17 U.S.C. § 101. Rather, the API packages are works of  
10          authorship written from scratch. (*See, e.g.*, RT at 621:7-623:16 (Reinhold).) Some decisions  
11          have treated as "compilations" works that represent collections and assemblies of uncopyrightable  
12          or copyrightable elements, regardless of how those elements were created. *See, e.g., Merchant*  
13          *Transactions*, 2009 U.S. Dist. LEXIS 25663 at \*46 ("coordination, selection, and arrangement of  
14          these field names, as well as the fields and field types themselves, formatting, and commenting,  
15          may be entitled to protection as a compilation so long as they 'are numerous enough and their  
16          selection and arrangement original enough that their combination constitutes an original work of  
17          authorship.'" (quoting *Satava*, 323 F.3d at 811). *See also id.* at \*58 (looking to selection,  
18          coordination and arrangement of both unprotected works and protected source code).

19          In that sense, the Java API packages are protectable as compilations, as well as works of  
20          authorship, particularly to the extent the Court concludes, for example, that method declarations  
21          are not copyrightable themselves. Notwithstanding such a determination, the selection and  
22          arrangement of so many declarations in such an elaborate and extensive structure represents  
23          copyrightable subject matter under this line of authority.

24                                   **(D) Was originality the only issue decided in *Kapes*?**

25          No. *Kapes* repeatedly emphasized the creativity involved in estimating the prices. *See,*  
26          *e.g., id.* at 1261. *Kapes* also discussed the idea/expression dichotomy and the merger doctrine.  
27          The court held that "the guiding consideration in drawing the line is the preservation of the  
28          balance between competition and protection reflected in the patent and copyright laws." *Id.* at  
29          1262 (quoting *Herbert Rosenthal Jewelry Corp. v. Kalpakian*, 446 F.2d 738, 742 (9th Cir. 1971)).

1 It concluded CDN could not copyright the idea of creating a wholesale pricing guide, but its  
2 prices warranted protection. The Court found this allowed CDN's competitors to create their own  
3 guides and compete, but still protected CDN's creation. *Id.* at 1262.

4 **13. When discussing use of the SSO in the 37 API packages in Android to**  
5 **achieve “compatibility,” what exactly are the parties referring to? Is it**  
6 **“compatibility” with programmers who write in the Java programming language?**  
7 **Or compatibility with pre-existing programs? If so, approximately what percent of**  
8 **pre-existing programs written for the Java platform are compatible with Android?**  
9 **Is it compatibility with the TCK? Or Java virtual machine? Or java compiler?**

10 The record reflects two definitions of compatibility. In the Java-specific sense, an  
11 implementation is only “compatible” if it passes the TCK. (*See, e.g.*, RT 977:22-978:1 (Google  
12 admission) TX 610.1 (Specification License); Gupta at RT 2306:6-2307:14 (“Q. A licensee was  
13 required to pass the TCK, even if they didn’t want to use the Java brand; is that right? A. Yes.”);  
14 RT 294:8-21 (Ellison); RT 366:21-25 (Kurian); RT 636:4-637:2 (Reinhold).) It is undisputed that  
15 Android has never passed an Oracle TCK. (RT 984:22-24 (Lee).)

16 The more general notion of compatibility is that programs built for one platform will run  
17 on the other. Professor Mitchell explained how Android is incompatible in this way as well. RT  
18 1331:16-1332:2, 2287:23-2288:5 (Mitchell). *See also* RT 1007:6-11, 1010:4-7 (Morrill); TX 383  
19 at 8 (Android FAQ 048. “Does Android support existing Java apps? / A. No. / 049. Is Android  
20 Java compatible? / A. No.”). Dan Bornstein testified ensuring Android would be “compatible”  
21 with Java in this sense “wasn’t a goal of the project.” (RT at 1783:15-22 (Bornstein).)

22 Oracle is aware of no metrics regarding the percentage of pre-existing programs written  
23 for the Java platform that are compatible with Android. The record refers to the fact that the byte  
24 code formats of Java and Android are different, such that a compiled Java program will not run,  
25 without modification, on Android, and vice versa, even if it only calls on the 37 copied packages.  
26 (*See* RT 2211:3-2212:2 (Astrachan); RT 2287:13-2288:5 (Mitchell).) More significantly, there  
27 are entire categories of incompatible programs because of packages that Google chose not to  
28 include. For example, Android lacks Java’s `java.awt.*` and `javax.swing.*` packages, which  
provide user interface capability. Compare TX 610.2 at `/jdk-1_5_0-doc/docs/api/overview-  
summary.html` with TX 767 at `packages.html`. Instead Android uses its own set of graphics APIs,

1 including android.app.\* and android.graphics.\*. (*See id.*) This means that any Java program  
 2 requiring use of a graphical user interface will not run on Android. Similarly, Android uses  
 3 different APIs for sound (javax.sound.\* packages are not present in package list in TX 767) and  
 4 for image input/output (javax.imageio.\* packages not present in package list in TX 767). So  
 5 Android is incompatible in this regard as well. Even printing to paper (javax.print.\*) is different  
 6 between the two platforms. (*See id.*)

7 The fact that Android wrote its own APIs to handle many of these capabilities further  
 8 demonstrates that Google's copying was by choice, not to achieve compatibility.

9 **14. Inheritance does not exist among packages, only within a class. True?  
 10 If not, why not?**

11 True. While a number of packages have sub-packages, RT 1219:18-1220:5 (Mitchell),  
 12 characteristics are inherited based on class-subclass relationships and interface relationships.

13 **15. Inheritance is a characteristic of a class that results from the  
 14 superclass-subclass feature of the Java operating systems. True? If not, why not?**

15 True, with the caveat that Java is more accurately characterized as an application  
 16 development platform rather than an operating system. A class can inherit directly from its  
 17 superclass, and indirectly from that class's superclass, and so on. (*See* RT 588:5-11 (Reinhold);  
 18 RT 1218:15-16, 1225:10-16 (Mitchell).) Interfaces can be used to relate different classes that  
 19 share common characteristics that are located in different packages. (*See* RT 589:13-18, 590:5-  
 20 23, 601:22-25 (Reinhold).) An interface can inherit directly from one or more superinterfaces  
 21 and indirectly from those interfaces' superinterfaces, and so on. *See* RT 1219:16 (Mitchell). A  
 22 class can directly inherit from only a single class, but can implement multiple interfaces.

23 **16. Assuming that a copyright protection does not extend to names, including  
 24 fully qualified names, and assuming that copyright protection does not bar others from  
 25 using identical input-output (argument-return) designations, such that Google was free to  
 26 use the identical names and identical input-output designations, what more did Google  
 27 allegedly copy from the 37 packages that is allegedly covered by copyright? Put differently,  
 28 assuming Google was free to do the foregoing, to what extent was Android's SSO dictated  
 by the rules of the basic programming language?**

29 Answering the first question, even if copyright protection does not extend to fully  
 30 qualified names and input-output designations, Google still copied the following: (a) Types (but  
 31 not names) in field declarations (*see* TX 984 at 221 (noting that field declarations must include

1 types); RT 602:22-603:2(Reinhold)); (b) Subclass/superclass relationships (“X extends Y”) (RT  
2 1218:15-19, 1225:10-16 (Mitchell)); (c) Interface implementation relationships (“X implements  
3 Z”) (*See* RT 589:13-18, 590:5-23, 601:22-25 (Reinhold)); (d) Package/sub-package relationships  
4 (RT 2285:12-15 (Mitchell)); (e) Specification text on which Google “based” its implementing  
5 code (RT 2219:7-18 (Astrachan)); and (f) the original selection, structure, sequence, and  
6 organization of the above elements, including the names and the argument-return designations.  
7 Google copied all of these elements into Android. (RT 1248: 25-1249:25 (Mitchell).)

8         Moreover, as discussed above, even if individual names or argument-return combinations  
9 were not protectable, and even if Google had copied no more, a combination of unprotectable  
10 elements is still eligible for copyright protection. *Satava*, 323 F.3d at 811.

11         Answering the Court’s second question, regardless of whether Google was free to do what  
12 the question assumes, Android’s SSO was not dictated by the Java programming language. The  
13 only constraints Google faced were that it was obligated to follow the grammar of the Java  
14 programming language (TX 984 chapter 18) as well as the non-grammatical constraints of the  
15 language, *e.g.*, a class or interface cannot extend itself or be declared more than once. (*See id.*)  
16 Google was also obligated to include, in some form, the 60 or so classes discussed in response to  
17 question 7 above.

18         None of this dictates how to design the API. If it did, every API would be the same. The trial  
19 evidence showed that APIs performing similar functions were design very differently. (*See*  
20 Response to Question 4 above.) Google’s expert admitted that Google could have designed its  
21 own APIs, and the irrefutable evidence in the record is that Google *did* design its own APIs for  
22 other packages. (RT 2213:8-19 (Astrachan).) The constructs of the programming language  
23 provide an opportunity for designing a rich and complex structure but do not require it. RT at  
24 619: 13-23 (Reinhold) (“very little organization or structure” required for virtual machine and  
25 computer”); *See also*: RT 634:10-25 (Reinhold); RT 565:3-16 (Screven) (“there is nothing in the  
26 Java language specification that requires that there be a class named tree, but there is a class  
27 named tree within—within the standard APIs.”); RT 1238:11-1240:20 (Mitchell) (API designer  
28 starts with a “clean slate”).)
